	eek 2 quiz	
	A program indexes a buffer after a pointer to that buffer has been used as a parameter to the free() function. This is	1 point
	A violation of temporal memory safety	
	An information flow violation A violation of spatial memory safety	
	Correct behavior	
	If the integer was used to perform pointer arithmetic	
	If the integer is passed as an argument to strncat	
	✓ If the integer was passed as a parameter to open()✓ If the integer is used as the denominator in a division expression	
	Which of the following are true about a language that uses garbage collection or some other automatic	1 point
	means (e.g., reference counting) for memory management? (Select all that apply.) The language will not have type safety violations	, point
	The use of automatic memory management will provide a safety benefit, but typically at the cost of some performance	
	Consider the following code: 1 - char *foo(char *buf) {	1 point
	<pre>char *x = buf+strlen(buf); char *y = buf; while (y != x) { if (*y == 'a')break; }</pre>	
	6 y++; 7 } 8 return y; 9 } 10 11 - void bar() {	
	11	
	The definition of spatial safety models pointers as capabilities, which are triples (p,b,e) where p is the pointer, b is the base of the memory region the pointer is allowed to access, and e is the extent of that region. Assuming characters are 1 byte in size, what is a triple (p,b,e) for the variable y when it is returned	
	at the end of the code? (&innut+4 &innut &innut+10)	
	∪ (απιματ+,απιματ,απιματ- <i>τ</i>)	
	(y,&input,buf)	
	Which of the following are true about a type-safe language? (Select all that apply.)	1 point
	 □ The language is object-oriented. □ The language's types are static, i.e., checked by the compiler before running the program 	
	✓ The language may be used to enforce information flow security, depending on the type system	
	✓ The language is sometimes memory safe, but not always	
	An engineer proposes that in addition to making the stack non-executable, your system should also make	1 point
	Ensure that memory is always deallocated Not make the program more secure, because attacker-controlled data cannot be stored in the heap	
	Make the program more secure by disallowing another location for an attacker to place executable code	
	What is the <i>best</i> choice of value for a stack canary, of the following options?	1 point
	The constant 0 The constant 7	
	A random value	
	A predictable value	
	attacker?	
	The code in libc is better than code the attacker would write	
	The injected code might have bugs There is no need to modify the application's executable code	
	There is no need to be able to execute (writable) data	
	In a return-oriented program (ROP), what is the role of the stack pointer? It's really no different than in a normal program	1 point
	It's like the program counter in a normal program It's like the allocation pointer used by malloc()	
	It's like the frame pointer in a normal program	
	flow graph because:	
	The attacker is not interested in corrupting direct calls	
	active the delegation of the second terms of t	
	CFI should be deployed on systems that ensure the code is immutable CFI should be deployed on systems that ensure the data is non-executable	
ı.	CFI should be deployed on systems that ensure the data is non-executable	1 point
1.	CFI should be deployed on systems that ensure the data is non-executable Programs that use CFI don't have direct calls Recall that classic enforcement of CFI requires adding labels prior to branch targets, and adding code prior to the branch that checks the label to see if it's the one that is expected. Now consider the following program: 1 * int cmp1(char *a, char *b) { 2 return strcmp(a,b); 3 }	1 point
	CFI should be deployed on systems that ensure the data is non-executable Programs that use CFI don't have direct calls Recall that classic enforcement of CFI requires adding labels prior to branch targets, and adding code prior to the branch that checks the label to see if it's the one that is expected.
